

USW200 – domestic back up system

The domestic back up system allows stored water to be pumped to a supplementary storage tank serving toilet cisterns from a direct pipe connection. If the storage tank is empty, or a power failure occurs the controls will automatically activate a solenoid valve to supply mains water to the storage tank.

The system requires plumbing connections to be made in 15mm push-fit pipe (EPB2315) between the submersible pump hose and the internally mounted controls. A mains water supply to the solenoid valve is also required. The storage tank and associated fittings are not supplied as part of the kit, but full details of the installation requirements are supplied.

All other connections between the control panel and storage tank are as for option one.

Comprehensive instructions are provided with each system kit, detailing the assembly, installation and commissioning procedures.
