A purpose-designed sound reducing drainage system that offers outstanding sound insulation properties.

Used in conjunction with the acoustic pipe brackets, the dBlue acoustic soil system is designed to reduce noise and acoustic vibrations to a level of 16dB at 4l/s*.

Suitable for use in multi-occupancy applications as well as hospitals, hotels and other commercial applications, where reduced noise levels are preferred.

**Product specification information**

This guide contains product specification details, design and installation information for the Marley dBlue Acoustic Soil range. Information on the complete range of Marley Plumbing and Drainage system solutions is available to download from marleypd.co.uk or via the literature hotline 01622 852585.

*Structural noise, using 110mm Phonoklip® bracket
Marley soil & waste systems

Acoustic soil – dBlue

Marley acoustic soil range with a layered pipe, provides quick, hygienic removal of sanitary waste water.

Used in conjunction with the acoustic pipe clips, the acoustic system is designed to reduce noise and acoustic vibrations to a level of 16dB at 4 l/s discharge rate. It is also lightweight, resistant to temperature change and is jointed using the push-fit ring seal method.

Features and benefits
- Light weight
- Easy to handle on site
- 16dB at 4 l/s discharge rate, when using 110mm Phonoklip® bracket
- Secure push-fit jointing system
- Quick and easy to install
- Provides quick and hygienic removal of sanitary waste water
- Dramatically reduce the sound of waste water
- Compatible with the Marley PVCu Soil and Waste system for branch connection
- High impact and temperature resistant

Key Product Information
- Size Range: 110mm and 160mm
- Temperature Rating: 95°C (Short term)

Typical Applications
Sound attenuated drainage systems in:
- Apartments
- Hotels
- Libraries
- Hospitals
- Public buildings
- Restaurants

PVCu Soil systems

The PVCu soil system is available in 82, 110 and 160mm push-fit and solvent weld options incorporating socketed and plain ended pipe.

110 and 160mm pipe support components have been designed specifically to support horizontal or vertical suspended PVCu pipework.

Pipes and fittings are also suitable for use as internal and external rainwater pipes to drain flat roofs and metal gutter systems on commercial and industrial buildings.

- Pushfit or solvent weld jointing options
- Quick and easy installation saving time and money
- All collar bosses are individually pressure tested to ensure joint integrity
- Hole-saw locator on all bosses for ease of installation

HDPE soil

The HDPE soil range is certified to BS EN 1519: 2000 (licence number KM 545820). An extension of the Marley soil & waste portfolio, the HDPE range offers an alternative solution to cast iron. The combination of the excellent material properties of HDPE with homogenous welded joints provide greater installation flexibility with a range of jointing options.

It is particularly suited for commercial applications or where a product with high impact or abrasion resistance is required, such as hospitals, hotels, schools, as well as residential buildings. HDPE will also cope with temperature variations of -40°C to 100°C making it ideal for external as well as internal installations.

For connection to Marley waste systems.

---

Available in blue only.

---

For the best performance of the products it is recommended that all connections are made using a solvent cement.
The dBlue Acoustic Soil system

Material formulation
A special material formula was developed for the dBlue system combining plastic and minerals (mineral fillers), which enabled enhanced acoustic and mechanical characteristics. Detailed chemical tests on a selection of raw materials making up the triple-layer dBlue system material formulation were conducted. Aside from the safe and fast discharge of sanitary waste water, dBlue reduces noise generated by the flow of waste water in pipework. The dBlue system is resistant to hot waste water flow and can also be installed at extremely low temperatures in winter. The pipe has been manufactured in three colours, to distinguish the different layers.

Triple-layer pipe structure (Fig. 1)
The most modern method of triple-layer PP pipe co-extrusion was used in the production of the dBlue system. This method means that the propagation of noise generated by waste water flowing inside pipework is severely limited by the nature of the pipe construction.

![Fig. 1](image1.png)

Each of the three layers making up the dBlue system has an individual function

Internal layer
- material: PP-B polypropylene with flame retardant
- colour grey
- resistant to high temperature +90°C [+95°C – short term]
- high chemical resistance
- smooth surface

Middle layer
- material: PP-H modified polypropylene
- colour white
- additionally reinforced with minerals
- noise reduction
- high stiffness

External layer
- material: PP-B polypropylene
- colour blue
- resistance to external tensions
- resistance to atmospheric factors
- smooth surface

Noise reduction in soil and waste systems
Every object in motion makes noise, transmitting its vibrations in the form of pressure or negative pressure waves, to the surrounding air. There are two types of noise in soil and waste systems:

Airborne noise – coming from pipelines, generated by waste water flowing inside. In this case, a soundproof soil and waste system should limit the propagation of airborne noise and keep it inside the pipes. This is achieved by using a special material formula (using minerals), a multi-layer pipe structure, the quality of manufacturing and correct installation. (Fig. 2)

Structureborne noise – coming from pipes and fittings as well as the system of fixing to the building’s structure. This sound comes from the noise inside the system, which being limited by pipes and fittings makes them vibrate (acoustic resonance). The resonance is transmitted through a system of pipe brackets to the building’s structure and heard in the neighbouring rooms as an irritating acoustic wave. In this case it is important to design the system of fixing pipes and fittings to the building’s structure in such a way that the transmission of the acoustic resonance to its walls is reduced to the minimum. (Fig. 3)

Vibrations and acoustic bridge
Numerous tests were conducted in Aliaxis R&D laboratories to confirm the above mentioned theories. The tests helped to determine the points where maximum acoustic vibrations are generated on the pipe (Fig. 4). As shown, the main area of their generation is the pipe and the branch which further transmits acoustic vibrations to the soil stack. The test confirmed that the type and location of pipe brackets as well as the system’s design and material formula are the most important factors in the soil and waste system noise reduction. Designing a stand (see image below) measuring vibrations transmitted by the pipe bracket to the building’s structure (acoustic bridge) was the next step. Parallel to work on the structure of the dBlue system, pipe brackets were designed especially for the soundproof soil and waste system. The main objective of the laboratory and prototype work was to develop a system of pipes, fittings and pipe brackets with the weight and wall thickness lower than in the traditional soundproof systems but with the greatest possible reduction of noise inside the system and its transmission to its surroundings.

![Fig. 2](image2.png)

![Fig. 3](image3.png)

![Fig. 4](image4.png)
Reduction of noise inside the pipe and its transmission

The triple layer system puts different material media in the way of the propagating noise, which causes partial absorption of sound waves and partial reflection towards and significantly reduces transmission to their surroundings. The absorbed and reflected waves cause acoustic resonance of pipes and fittings. The greater height inside the building, the more dynamically the resonance (Fig. 5) increases towards the flowing waste water and is transmitted through the fixed system onto the building’s structure. Construction barriers subject to the acoustic resonance transmission cause its transmission to neighbouring rooms in the form of sound waves. The dBlue system’s structure along with pipe brackets is responsible for the maximum reduction of this acoustic phenomenon (Fig. 6). The acceptable noise level in the above mentioned rooms (a living room, a hospital ward, bedroom or a hotel room) is set at the national acoustic safety standards for buildings. These are the places that are particularly protected against noise at the design stage. In contrast, kitchens and bathrooms are the places where pipes are usually located. However, here the noise coming from the soil and waste system is negligible compared with the equipment normally operating in these rooms so it is not subject to limitations to the same degree as the above mentioned rooms designed for frequent stay.

Limiting noise propagation
- triple-layer wall structure

Preventing transmission of acoustic vibrations
- between pipes and fittings
- tight socket/gasket connection

Acoustic clips
- acoustic bracket options

*Tests on the reduction of noise coming from soil and waste system carried out in the Institute for Building Physics Fraunhofer Germany, dBlue showed structural borne noise at the level of 16dB at 4l/s under the test conditions.

Marley dBlue – Fraunhofer test

Test and measurements of noise emitted by the soundproof dBlue system were conducted according to the European standard EN 14366 “Laboratory measurement of noise from waste water installations”.

The diagram below presents noise measurement and its methodology inside the dBlue system. The test stand, diameters and types of components used are described in the standard. Water introduced into the system on the NK(f) floor and received on the C floor was the tested medium. Acoustic tests are conducted in rooms PP(t) and PP(f) and the least favourable boundary conditions are assumed in the comparative analysis with other soil and waste systems or other sources of noise. The boundary conditions are as follows:
- measured flow in the soil and waste system Q = 0.5, 1, 2 and 4
- pipe diameter DN=110 mm (most frequent diameter)
- measurement taken on the lowest floor, in room PP(t) – room marked red in the diagram; safety standards determine and require the lowest noise levels at this point (room neighbouring the soil stack)
- partition wall – weight: 220 kg/m2

Diagram summarises and visually presents noise measurement for dBlue soil and waste system carried out in the least favourable boundary conditions. Taking into account the assumptions of the above-mentioned test procedure (EN 14366) the maximum levels of noise of dBlue installation were compared for the two most important flow rates.

### Acoustic safety of rooms

**Noise in our everyday surroundings**

It is useful to compare the dBlue system's noise reduction and acoustic vibration suppression properties to everyday noise around us. Subject to the test procedure on the level of noise reduction, conducted at Fraunhofer Institute in Germany, according to EN 14366. The dBlue system showed the emitted structural noise level of only 16dB at 4l/s. The diagram below refers the value of 16dB to the noise present in our everyday surroundings.

The diagram below also indicates individual noise levels and their potential effect on human health.

### Everyday noise levels and their effect on human health.

#### Acceptable noise levels

The acceptable noise level that a human being can be exposed to while performing everyday activities and relaxing is described as "the threshold noise level value". According to the valid regulations, there are two categories of noise tests:

**Category I:** Noise measured outdoors, i.e. in the neighbouring area, surroundings and open space. According to European Directive No.2002/49/WE, generally speaking, the noise acceptable in a built-up area at daytime is 60dB and at night (between 10.00 pm and 6.00 am), 50dB.

**Category II:** Noise measured indoors. "Building acoustics. Protection of rooms inside buildings against noise. Acceptable indoor sound level values".

The table below presents several examples of the acceptable sound level in rooms used on a daily basis.

<table>
<thead>
<tr>
<th>KIND OF ROOM</th>
<th>Acceptable average level of sound-noise reaching the place from the building’s technical equipment and other equipment inside and outside of the building</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rooms designed for mental activities that require intense concentration</td>
<td>30dB – 35dB</td>
</tr>
<tr>

<td>30dB – 25dB</td>
</tr>
<tr>
<td>Kitchens and sanitary rooms in apartments</td>
<td>40dB – 40dB</td>
</tr>
</tbody>
</table>

An organ of hearing like the human ear is made to receive not only very quiet noise but also to withstand very loud sounds. As the diagram shows, the difference between the level of noise emitted by the dBlue acoustic soil system and a loud conversation is 14dB. The minimum noise level detected by the human ear is 3dB. This means that an increase in the noise level by 14dB makes a significant and noticeable difference for the ear; the difference later turns into irritating noise. While determining acceptable indoor noise standards for the construction industry it is assumed that the minimum noise reduction that can improve room acoustics and human ear perception is 5dB.

Therefore, the acceptable noise standards for the construction industry described in the next section differ by 5dB in each room.

The Building Regulations Approved Document E (2010) stipulates acoustic requirements of 45dB or less. This Building Regulation applies to any kind of building used as a dwelling, including houses and apartments; and rooms for residential purposes, such as students and nurses accommodation, nursing homes and hotels. It also applies to dwellings that have been created as a result of a conversion or material change of use.

The Scottish Technical Handbook (2016), section 5.1.2 stipulates acoustic requirements of 53dB.
Structure of dBlue acoustic pipe bracket

In order to provide the described reduction of the acoustic bridge and transmission of vibrations coming from the dBlue system, a range of acoustic pipe brackets have been designed with dual fixings, allowing easy conversion from anchor to guide.

The Phonoklip® bracket

A patented acoustic body bracket, encompassing a unique body section which absorbs noise generated from pipework into the building structure. Designed within the Aliaxis R&D laboratory.

- 110 and 160mm options
- Vibration section (integral)
- M8 thread on 110mm and M10 on 160mm
- Colour: grey

Supplied with a system lock with a locking screw (M-6) and a spacer.

In order to obtain a guide point bracket, insert a pipe in a bracket and lock it with a screw and a spacer.

The dBlue bracket

Elastomer inlayed acoustic metal bracket, suppressing pipework noise into the building structure.

- 110 and 160mm options
- Rubber lined
- M10 thread
- Colour: blue

Supplied with a system lock with a locking screw (M-6) and two spacers.

In order to obtain a guide point bracket, insert a pipe in a bracket and lock it with a screw and two spacers.

Case study

St John’s student accommodation, Northampton

When the University of Northampton embarked on a multi-million pound project with main contractor Kier Construction, to build a new student accommodation building, it required a plumbing and drainage manufacturer that could provide solutions for a variety of applications. With an extensive product portfolio and an expert technical team, Marley Plumbing and Drainage was ideal for this project.

“We chose Marley’s competitively priced dBlue, HDPE and PVC Soil and Waste products for this project because of their durable, yet lightweight constructions, which ultimately led to easier handling on site and – going forward – the ability to withstand high daily usage.”

Bob DeGennaro, Integral
Methods of jointing

The principal method of jointing 110 and 160mm dBBlue pipes and fittings is by ring seal. Some components in the range are solvent welded.

Sanitary pipework design

All sanitary pipework systems should be designed in accordance with BS EN 12056: 2000, Parts 1 to 5.

Bends at the base of stacks

Bends at the base of vertical stacks should be of long radius and have a minimum centre line radius of 200mm on a 110mm nominal size stack. Two 45° radius bends may also be used as an alternative to provide the change of direction and connection to the building drain. The same design principle should also be adopted where offsets occur in stacks of one or more storey height.

Branches at the base of stacks

For single dwellings up to three storeys high, the distance between the centre line of the lowest branch connection and the invert of the drain should be at least 450mm. For multi-storey systems up to five storeys high, the minimum distance should be 740mm and for systems higher than five floors no connections are permissible at ground floor level. Where this occurs a separate stub stack should be provided to serve the ground floor or individual appliances should have their own separate connection to the building drain.

Stub waste

This technique is often used to connect isolated ground floor waste appliances such as basins, baths, shower trays and sinks to eliminate exposed pipework or low level ducting. The 110mm unventilated drain is terminated at finished floor level with a reducer and boss adaptor to suit the size of waste from the appliance.

Offsets in stacks

Offsets in the wet portion of a discharge stack should be avoided whenever possible but where they have to be fitted a large radius or two 45° bends should be used to create each change of direction. Offsets in lightly loaded stacks up to three storeys high do not require offset venting but on multi-storey buildings this may be necessary depending on the loading of the stack and the numbers of floors above the offset. The principles previously described for bends and branches at the base of a stack should also be applied.

Prevention of cross-flow

Where small diameter branch waste pipes connect to a discharge stack they must be arranged to eliminate the risk of cross-flow from one branch to the other. A branch creates a no entry zone for opposing waste connections, which varies depending on the stack diameter. No connections should be made within the restricted zone although entry is permissible on the centre line of the boundary directly opposite or at right angles.

Design

To prevent cross-flow from a large diameter branch to a smaller waste connection, the latter should be made to the stack at or above the centre line of the larger branch, at right angles or at least 200mm below the restricted zone. Entry is permissible on the boundary centre line directly opposite or at right angles.
Design

Jointing techniques
The ring seal has been successfully employed as the principal method of jointing large diameter PVCu pipes and fittings since their introduction over thirty years ago. This particular technique has proved extremely reliable as the joint can accommodate thermal movement that will occur as a result of temperature variations. An expansion gap of between 5-10mm should be allowed within each ring seal socket as each full length of pipe is installed and fixed.

Vertical pipe support
In order to maintain good acoustic properties, the dBlue system should be installed together with specially designed acoustic pipe brackets, details of which can be found on page 16.

Horizontal pipe support
The Marley pipe support range was developed to meet the specific requirements of suspended sanitary pipework and drainage systems. Manufactured in zinc electro plated mild steel for internal use, the versatile range of components can be assembled to provide a robust, lightweight system suitable for most applications. The system also provides suitable control of expansion and contraction.

The arrangements of brackets and channel supports have been extensively tested and the assembly techniques used have been successfully employed on many domestic and commercial installations. Three different support methods are described and the recommended support centres are shown in the following table for each option.

Single support
Recommended for waste or larger diameter pipework fixed within 500mm of the floor soffit. (Fig. 8)

Continuous channel support
Suitable for use where pipework is fitted within 750mm of the floor soffit with structural fixings provided at a maximum of 1.2m centres. (Fig. 9)

Double support
Developed for use with larger diameter pipework fixed within 1.0m of the floor soffit. (Fig. 10)

Pipe brackets
The 110 and 160mm two piece pipe brackets are designed to fit round the ring seal socket of a pipe or fitting. Where intermediate support brackets are located, the SC621 PVC barrel clip collar is used as a spacer sleeve between the pipe and bracket.

Angle and side bracing
Angle brackets should be provided at 6m centres to prevent linear and thermal movement. Side bracing may also be necessary on long runs where there are no side connections to eliminate lateral movement.

Vertical pipes
The transition between vertical and horizontal pipework should be achieved using two 45° bends or a single 87.5° long radius bend with a support bracket positioned as close as possible.

Branch connections
All branch connections into horizontal pipework should be made at 45° to ensure the discharge is swept in the direction of flow.

Structural fixings
It is recommended that 6mm rawlbolt or similar proprietary fixings be used as a spacer sleeve between the pipe and bracket.
Installation

Cutting pipes and jointing
Prior to cutting the pipe and jointing it to another pipe or fitting, measure the necessary pipe section allowing for the pipe socket depth.

Cut the pipe using a pipe cutter (Photo 1) or a fine-toothed saw (Photo 2), with particular attention to keeping the angle 90°. Another important factor prior to making the connections is to bevel the pipe end properly, using a chamfering tool or coarse file to provide a 15° bevel on the end of the pipe. (Photos 3 & 4)

When connecting the pipe with a fitting or the socket of another pipe, push the connected pipe to the insertion depth (Photo 5) and mark a line on the edge of the socket and the connected pipe (Photo 6).

In order to allow for thermal movement, an expansion gap of between 5-10mm should be allowed within ring seal joints as each full length of pipe is installed and bracketed accordingly to ensure the gap is maintained (Photo 7). Using a level (Photo 8), determine the length of the Marley dBlue soil stack. On the run line, measure the points (Photo 9) where the pipe brackets will be fixed.

Next, drill holes applicable for the diameter of fixing (Photo 10) on the pipe line. Affix a drop in anchor & thread and mount the pipe bracket by screwing it clockwise, so that the bracket is firm against structure. (Photo 11 & 12).

In the final stage, put the pipe or fitting inside the pipe bracket under socket and connect the open pipe bracket (Photo 15).

Final installation using Phonoklip® bracket and dBlue bracket. (Photo 16 and 17)

NOTE:
If using a backplate or channel system, bracket must be also threaded firm against the backplate or channelling.

NOTE:
Prior to making socket connections, lubricate the pipe end and the seal in the socket to facilitate inverting the spigot into the socket.
Installation

Full dimensional standardisation

With a view to facilitating installation works and connecting the Marley dBlue system to other soil and waste systems as well as connecting those systems to the Marley dBlue soil and waste system, full dimensional standardisation of the system was maintained, according to EN 1451. This means that connections of all diameters can be made without any need to use adapting connectors for non-standard diameters. Basic examples of connections are presented opposite.

Akavent fitting – operation

The Akavent is designed for high-rise buildings. Its construction separates the main stream of waste flowing through the stack from waste coming in from side stacks; this prevents the occurrence of “hydraulic plug”. It has additional internal ventilation which balances pressure and ensures appropriate supply of air without the need of using increased diameter or additional ventilation stack.

Waste flowing through the fitting is diverted towards the walls of the arch thanks to which the velocity of the waste is reduced. See below.

Penetration through construction barriers

Insulating soil and waste ducts across construction barriers (Detail ‘W’) is an important part of the planning and design process. It is aimed at safeguarding the users against the “acoustic bridges” in construction barriers. These are points where a duct being in contact with the construction of a building transfers acoustic vibrations generated by the flowing waste.

The below details show the correct penetration of an acoustic duct through a wall barrier. Each penetration should be secured with a sleeve (3 – 5 mm) made of material ensuring proper acoustic and moisture insulation.

For further information on Akavents, please see our website. For details on our fire collar range, please speak to our Technical Service department.

Standards

British & European Standards

BS EN 1451
Plastics piping systems for soil and waste discharge (low and high temperature) within the building structure. Polypropylene (PP). Specifications for pipes, fittings and the system.

BS EN 1329-1
Plastics piping systems for soil and waste discharge (low and high temperature) within the building structure – PVCu.

BS EN 1411
Plastics piping and ducting systems. Thermoplastics pipes. Determination of resistance to external blows by the staircase method.

BS EN 1055
Plastics piping systems. Thermoplastics piping systems for soil and waste discharge inside buildings. Test method for resistance to elevated temperature cycling.

BS EN 1054
Plastics piping systems. Thermoplastics piping systems for soil and waste discharge. Test method for air tightness of joints.

BS EN 681
Elastomeric seals. Material requirements for pipe joint seals used in water and drainage applications.

BS EN ISO 9001: 2008

BS EN ISO 14001: 2004
Environmental management systems. Requirements with guidance for use.

Approvals

dBlue has been approved by the following certification bodies:
Designing the most efficient drainage system for a project is a skill for which the Marley Technical Services team are renowned. Marley Plumbing & Drainage provide technical support to all those involved with the specification and installation of our products.

Our technical team can help you specify the system you need

Years of experience mean that we can support you throughout your tender process and assist with any technical and installation requirements.

PVC Soil

Standard PVCu soil systems to BS EN 1329: 2000. Ideal for domestic and commercial applications, including branch connections to other materials. Available in 82mm, 110mm and 160mm, ring seal and solvent weld jointing variants.

HDPE

Marley Akatherm HDPE is a drainage system which offers an alternative solution to cast iron. It is particularly suited for commercial applications or where a product with high impact or abrasion resistance is required, such as hospitals, hotels, schools, as well as residential buildings. HDPE will also cope with temperature variations of -40°C to 100°C making it ideal for external as well as internal installations.

Sankey

The Multikwik brand is known and trusted by plumbers for its sanitary frames, cisterns, traps, compression waste systems and market leading range of pan connectors. Complementing the Marley range it provides an excellent solution to modern bathroom design with a wide choice of product options.

Foundry Finish

Foundry Finish is a cast-iron effect PVCu system, offering a great combination of traditional good looks with modern lightweight materials.

The Marley Plumbing & Drainage range of underground systems include the solid wall range, predominately for round the house drainage and Quantum structured wall range for sewer and highway drainage applications.

The Marley rainwater range is the most comprehensive available.

Five gutter profiles and three downpipe options provide a rainwater solution for any application. Advanced Life4 technology on four of the key profiles, coupled with the benefits of the Easyclip and notching capability combine to make the Marley rainwater range the most comprehensive available.
